Contract NAS3-20578

FOREWORD

The compressor designs described herein were prepared under NASA Contract NAS3-20578 by Pratt & Whitney Aircraft Group, Commercial Products Division, United Technologies Corporation, Hartford, Connecticut under the direction of Mr. N. T. Monsarrat, Program Manager. The NASA Project Manager was Mr. R. S. Ruggeri, NASA-Lewis Research Center, Fluid System Components Division, Fan and Compressor Branch. The work was performed during the period 20 October 1976 through 30 June 1979. The authors wish to acknowledge the participation and significant contributions in the fulfillment of this contract by the United Technologies Research Center test facilities operations group under the direction of Mr. C. I. Crockett.

SUMMARY

The Core Compressor Exit Stage Study (Contract NAS3-20578) is being conducted to demonstrate improved blading for the rear stages of highly loaded advanced compressors for advanced aircraft engines. The basic technology, developed at Pratt & Whitney Aircraft, has been shown to reduce endwall losses, at least for moderate or more conventional hub-tip ratios. The objective is to reduce endwall losses through the use of low aspect ratio blading. The intent is to demonstrate this objective by means of design and subsequent testing of two advanced three-stage compressors of similar design but having significantly different aspect ratios. This report describes the aerodynamic and mechanical designs of these two compressors.

The 3S1 compressor is a test model of the last three stages of an eight-stage compressor identified during an earlier NASA contract as an optimum configuration for commercial service in the 1980's. The 3S2 compressor is basically the same as the 3S1 configuration, but has a fifty percent higher aspect ratio: the aspect ratio of the 3S1 configuration is 0.81; the aspect ratio of the 3S2 is 1.22. Both configurations have a mean wheel speed of 167 m/sec (547 ft/sec), a flow capacity of 4.30 kgm/sec (9.47 lbm/sec), and a tip diameter of 60.96 cm (24.0 in.). Circular arc mean camber line airfoils with 65 series thickness distribution were chosen for both compressors.

This report presents calculated design performance and design parameters such as incidence angles, diffusion factor, and static pressure loading factor. Aerodynamic design parameters, airfoil geometry on conical surfaces, and blade and vane manufacturing coordinates are presented in tabulated form in the appendices.

INTRODUCTION

Engine cycle studies conducted to determine technology requirements for advanced aircraft engines of the 1980's indicate that core compressors for these engines will have to operate at high pressure ratios and with increased overall efficiency compared with present designs. When considering the many factors involved in the design of these advanced compressors (weight, cost, number of parts, etc.), this implies the need for higher blade tip speeds and greater pressure-rise capability per stage. The design of the rear stages for these compressors presents a particularly difficult problem compared with current conventional designs because (1) the hub/tip ratios will be considerably higher (exceeding 0.9) than current practice and (2) the

blade aspect ratio will be low. The combination of these two factors makes secondary flow considerations extremely important and must be properly accounted for in the design process in order to achieve reduced endwall losses and increased efficiencies in rear stages of these compressors. Conventional compressor design practice may not be adequate to account for the strong secondary flow effects.

Techniques have been developed by Pratt & Whitney Aircraft for designing compressors with reduced endwall losses for lower hub-tip ratios. These techniques involve optimization of aspect ratio and camber changes in the blade end regions in order to reduce endwall loss as well as maximizing average spanwise blade loading. However, little experience is currently available to substantiate the technique at high hub-tip ratios.

The objective of the present core compressor exit stage study is to demonstrate improved blading design for the rear stages of high loaded advanced compressors through the design and subsequent testing of two three-stage compressor configurations in a realistic environment. One configuration (designated 3S1) is basically a test model of the last three stages (stages 6, 7, and 8) of the compressor identified in a previous NASA Contract Study (NAS3-19445), "Advanced Multistage Axial Flow Compressor (AMAC) Design Study," as an optimum compressor for commercial engines of the 1980's (ref. 1). Configuration 3S1 is designed for a pressure ratio of 1.357 and has an average blade aspect ratio of 0.81. Configuration 3S2 is very similar in design to configuration 3S1 ($\text{PR} = 1.324$), but has an aspect ratio of 1.22. Both compressors were designed for a corrected flow of 4.30 kg/sec (9.47 lbm/sec), a corrected mean wheel speed of 167 m/sec (547 ft/sec) and a diameter of 60.96 cm (24.0 in.).

This report presents the detailed aerodynamic and mechanical design for both the 3S1 and 3S2 compressors together with a description of the methods and procedures used.

AERODYNAMIC DESIGN

DESIGN PARAMETERS AND PROCEDURE

A schematic drawing of the 3S1/3S2 compressor is presented in Figure 1. The average blade aspect ratio of the 3S1 configuration is 0.81; the overall pressure ratio at design speed is 1.357; and the average diffusion factor (D-factor) is 0.529. The aspect ratio of the 3S2 configuration is 1.22; the overall pressure ratio at design speed is 1.324; and the average D-factor is 0.491. The higher pressure ratio of the 3S1 compressor is in recognition of the increased capability believed to exist at lower aspect ratios. The design mean wheel speed of both configurations is 167 m/sec (547 ft/sec); flow capacity is 4.30 kg/sec (9.47 lbm/sec); and the tip diameter is a constant 60.96 cm (24.0 in.). These design parameters were influenced by the capabilities of the existing test facility. The principal aerodynamic design parameters of the AMAC, 3S1, and 3S2 compressors (3-stage) are listed in Table I.

*D Factor Avg. = Mass Avg. D Factor From Streamline Analysis Computer Program For Each Blade Row Divided By The Number Of Blade Rows

The aerodynamic design was performed in three steps. First the analytical design system was adjusted to ensure performance agreement with data from tests of three-stage compressors similar to the 3S1 configuration. Next a preliminary effort based on a meanline approach provided an approximate flowpath and average values of aerodynamic parameters. Finally, a detailed fullspan design which utilized a streamline-calculation procedure established the blading geometry and finalized the flowpath dimensions.

BLOCKAGE, LOSS AND TURNING EVALUATION

Data from three previously tested compressors (referred to as TR-1, TR-2, and TR-3) with similar work and flow coefficients and loading levels were used to adjust general cascade loss and turning criteria and blockage factors. The effort utilized the Pratt & Whitney Aircraft streamline-analysis computer program and cascade correlation system, which was included as an integral part of the computer program. The streamline analysis program defined velocity vectors and flow conditions by means of an axisymmetric compressible-flow solution of the continuity, energy, and radial equilibrium equations with curvature, enthalpy, and entropy gradient terms included in the equilibrium equation (see Appendix B).

The data from the three tested compressors included (1) spanwise total temperatures at the compressor inlet, at each stator leading edge, and at the compressor exit, (2) spanwise total pressure at the same locations, and (3) outer diameter static pressure measurements at each blade row leading edge, at each blade row trailing edge, and at the midgap between each blade row. The streamline analysis program determined the rotor turning and loss that matched the test data and then compared these results with those predicted with the cascade system based on the airfoil geometry. The differences between the results indicated by the test data and those predicted by the cascade system were split equally between the rotors and stators and applied as an adjustment to the cascade system for each blade row. The adjustments required were the same for all three tested compressors.

Blockage adjustments were established in a similar manner. Velocity and static pressure profiles that matched static pressures measured at the outer diameter were computed, and a blockage factor for each blade row was calculated from these profiles. All three compressors had similar blockage distributions. The blockage distribution shown in Figure 2 was adopted for the design of 3S1 and 3S2 and is typical of the distributions determined from tests of TR-1, TR-2, and TR-3.

The validity of the adjustments to the cascade system and the blockage distribution was checked by using the adjustments to recalculate the performance of the three tested compressors and then comparing the calculated performance with test data. Two sets of checks were made for each of the three tested compressors. The first check compared

test and predicted total temperature and pressure profiles at the design point. As shown in Figures 3, 4, and 5, the test and predicted profiles matched well. The second check compared the shapes of the 100 percent design speedlines. Good agreement was obtained as shown in Figure 6. The slightly steeper predicted speedline shapes noted are probably a result of small blockage variations over the speedline, which were not accounted for because they would not significantly affect the design.

PRELIMINARY DESIGN

The primary purpose of the meanline design was to establish a preliminary flowpath and stage pressure ratio distribution consistent with a selected 15 percent surge margin. Average stage values of flow coefficient, reaction, and diffusion factor and the midspan values of solidity and aspect ratio of the 3S1-configuration were set similar to the AMAC compressor. Because the capabilities of the test facility limit design speed, flow rate, and the flowpath outer diameter; wheel speed, Mach numbers, and pressure ratios are lower than those determined for the AMAC study program. However, parameters such as loading, flow coefficient, and work coefficient were maintained (see Table I).

A preliminary flowpath and a set of meanline air triangles were calculated from the above information and the blockages established as previously described. The resulting flowpath was slightly divergent, but was reset to a constant inner diameter and outer diameter configuration, which necessitated minor changes in air angles and less than one percent change in the flow coefficients. The overall pressure ratio was determined using Pratt & Whitney Aircraft's design rules of loading capability versus average aspect ratio to yield the design average D-factor and for the selected 15 percent surge margin. Stage pressure ratio distribution was determined by maintaining the same stage-by-stage D-factor distribution established for the AMAC compressor at the 3S1 design overall pressure ratio.

DETAILED DESIGN

Compressor 3S1 Design

Utilizing the average aerodynamic parameter determined by the meanline analysis, a fullspan blade-row-by-blade-row design was performed by means of a streamline analysis computer program that incorporates the cascade correlation system. When used in the design mode, the cascade correlation system determines the airfoil metal angles and aerodynamic losses. Airfoil series, solidity, thickness-to-chord ratio, inlet and exit air angles, Mach number, and axial velocity density ratio are required inputs. Circular-arc mean-camber-line airfoils with a 65 series thickness distribution were chosen because of their excellent low-speed characteristics and to be consistent with the AMAC design.

The spanwise solidity was determined by combining the mean solidity and chord utilized in the meanline design with a constant chord design. Because of structural considerations, spanwise thickness-to-chord ratio was modeled after the previously tested compressors (TR-1, TR-2, and TR-3). Inlet and exit air angles, Mach numbers, and axial velocity density ratios were calculated by the streamline analysis program (flow, speed, pressure ratios, reactions, and blockages determined beforehand and the losses predicted by the cascade system were required inputs). Design incidence angle for all blade rows was set for minimum loss. The solidity, thickness-to-chord ratio, and blade metal angles for the 3S1 compressor airfoils are shown in Figures 7 through 14 and the values for the 3S2 design (described in the following section) are also shown for comparison.

The selection of the airfoil leading and trailing edge angles are affected by the flow conditions in the endwall region as well as in the freestream (core flow). The cascade system in the freestream mode sets the incidence angle relative to minimum loss and the estimated deviation angle. Leading edge and trailing edge overcambers were applied at both endwalls to align the blading to the anticipated endwall flow and to ensure an acceptable discharge velocity profile. The blading, established previously for design conditions, was reanalyzed in an offdesign analysis to estimate incidence angles at the predicted surge point. As a result, a slight overcamber (increased incidence angle) was added at the root leading edge of the second and third stage blading in order to prevent premature surge. Final values of incidence and deviation angles are presented as functions of percent span in Figures 13 through 18.

The predicted efficiency shown in Table I was produced by a meanline efficiency prediction program based on analytical model correlations of compressor data--and is in basic agreement with the overall test efficiency of the majority of Pratt & Whitney Aircraft compressor experience. Two-dimensional cascade, endwall, and tip clearance loss effects are included. The efficiencies shown in the streamline design summary (Appendix C) result from a design procedure derived only for airfoil geometry selection. The resultant average and spanwise shape of efficiency are not predictions and do not, therefore, agree with the meanline program results.

Manufacturing limitations for cast aluminum airfoils indicated that the minimum permissible radius for the blade and vane leading and trailing edges was 0.23 mm (0.009 in.). The constant inner and outer diameter flowpath established during the meanline design was retained in the final design. The axial spacing between blade rows in terms of axial spacing-to-chord ratio was modeled after conventional compressor rear stages.

The airfoil aerodynamic summary for the blades and vanes for the three 3S1 compressor stages is presented in Appendix C, pages 50 to 56;

airfoil geometry on conical surfaces is presented in Appendix D, pages 67 to 73; and manufacturing coordinates for sections normal to the stacking line are presented in Appendix E, pages 82 to 102.

Compressor 3S2 Design

The 3S2 compressor has a 50 percent higher aspect ratio than the 3S1 compressor, but the designs are essentially the same. A comparison of 3S1 and 3S2 compressor design parameters is presented in Table I.

The blockages and the adjustments to the cascade system used for 3S1 compressor were also applied to the 3S2 compressor. The only difference in the meanline design was that the 3S2 design loading level was reduced, but the stage distribution was maintained to make it consistent with the Pratt & Whitney Aircraft aspect-ratio aerodynamic-loading correlation. The 3S2 airfoil designs were established by means of the same procedure used for 3S1.

The blade-row-by-blade-row spanwise distributions of loss, deviation, incidence, loadings, thickness ratio, solidity, and metal angles from the streamline design for the two configurations are compared in Figures 7 through 24. Leading and trailing edge radii were maintained at a constant 0.23 mm (0.009 in.). The flowpath O.D. and I.D. were not changed, but the axial spacing between all the blade rows was scaled by the chord change between 3S1 and 3S2 so that each blade row would be affected by equivalent values of unmixed wake blockage. The airfoil aerodynamic summary, the airfoil geometry, and the manufacturing coordinates for the 3S2 compressor are presented respectively in Appendix C pages 57 to 63; Appendix D pages 74 to 80; and Appendix E pages 102 to 123.

MECHANICAL DESIGN

MECHANICAL DESIGN PROCEDURE

The basic mechanical design of 3S1 and 3S2 compressors has been used successfully in many previous test programs. The design consists of an assembly of interlocking aluminum rings forming the compressor case and a set of aluminum wheels keyed to a central shaft forming the compressor hub. Simplified techniques were employed in the mechanical design of such special parts as flowpath cases, disks, and blade retainers. Steady-state stress analyses were performed for all blading and for all rotating parts to ensure structural integrity. A schematic of the compressor assemblies is shown in Figure 1.

OUTER CASING DESIGN

Case components include inlet guide vane and stator carrier rings, rotor tip shroud rings, spacer rings, and front and rear end flanges. Axial widths of individual rings are different for the 3S1 and 3S2

designs because of the chord lengths of the particular airfoils. End flanges are heavy steel members positioned at the front and rear of the case. Long tie bolts compress the interlocking case rings between the end flanges to form a structurally rigid compressor case assembly.

ROTATING DRUM DESIGN

An existing compressor hub is utilized, consisting of a rotor assembly supported by bearings at the front and rear of the compressor. The rotor assembly consists of a stack of aluminum rotor blade carrier and spacer wheels keyed to a central shaft that is threaded at both ends. The parts are secured in place on the shaft by steel end-plates, spacer sleeves, and a large nut.

The steel front and rear bearing assemblies are supported through the case end flanges by four steel bolts. Precision grease-packed bearings are utilized. The bearings and the bearing support assembly have been utilized in other three-stage compressor programs. Thrust loads on the bearings are compensated for by means of a vented chamber surrounding the rear bearing. Leakage between the bearing compartments and the flowpath is controlled by a series of knife edge seals on the rotating members and opposing soft abradable seals on nonrotating surfaces.

AIRFOILS

All blading is cast to the specifications of the aerodynamic design. The blade specifications are presented in tabulations of profile geometries at incremental radial stations from hub to tip for all blading stations and of corresponding stagger angles, stacking points, and section properties. Thirteen radial stations were selected to define the blade shape for each blade row.

Casting was selected as the most cost effective means for obtaining duplicate blading in relatively small lots. The blade cast material is A356-T6, an aluminum alloy used successfully for cast blading in similar compressor designs since 1968.

Blading attachment is accomplished by means of a bolt, as shown in Figure 25, which secures an integral stud on the blade or vane into a corresponding recessed hole in the blade or vane carrier. This method of blading installation, which is mechanically simple and provides the option to restagger any or all blade rows, has been used successfully in previous programs. A photograph of typical cast aluminum blading, including mounting pads, for a three-stage compressor is shown in Figure 26. Typical rotor and cantilevered stator assemblies are shown respectively in Figures 27 and 28. All airfoils were designed to permit trimming to the specified tip clearances after assembly.

3S1 AND 3S2 AIRFOIL STRESS ANALYSES

Static stresses for the IGV, R1, R2, R3, S1, S2, and S3 blading were calculated to verify that the blade designs were adequate for stresses at design loadings. The stress analyses included a bending analysis and an air load analysis. The bending analysis assumed that the air load passes through the shear center, thus applying no torque to the airfoil. Rotor and stator airfoil loads and moments, caused by pressure and flow, were calculated in the axial, tangential, and meridional directions.

The maximum airfoil stresses, which occur at the rotor hub and at the stator outer diameter, are presented in Table II. For purposes of comparison, Table II also contains stress levels calculated for the first-stage rotor of a Pratt & Whitney Aircraft low aspect ratio compressor that operated successfully for 40 hours and which utilized similar A356-T6 cast aluminum blades.

Displacements, strains, and stresses in compressor rotating hardware were calculated to verify that these components are adequate for operation at design speed. Maximum stresses are summarized in Table III. The rotating components were analyzed as bodies of revolution subjected to axisymmetric inertia loading caused by the component itself and by the blades and blade attachment fittings at 6200 rpm (110 percent design speed). Displacements, strains, and stresses in both the tangential and radial directions were obtained by a finite element analysis. All disks were mass balanced, resulting in rim designs which equalize radial growth relative to their planes of rotation. The elimination of this possible hub distortion permits compressor operation with minimum blade tip clearances. Table III also gives the calculated stress levels of a typical rotor wheel and spacer in the same compressor used for the comparison in Table II.

TE	- Trailing edge
TER	- Trailing edge radius
U	- Rotor tangential speed
V	- Air velocity
W	- Weight flow
y_p	- Airfoil coordinate of pressure surface normal to chord line
y_s	- Airfoil coordinate of suction surface normal to chord
y_{CSL}	- Vertical distance to airfoil stacking line from chord line
y	- Length along calculation station

APPENDIX A (Cont'd.)

- z_c - Airfoil coordinate parallel to chord line
 - z_{CSL} - Horizontal distance to airfoil stacking line from leading edge along chord line
 - β - Absolute air angle = $\cot^{-1} (V_m/V_\theta)$
 - β' - Relative air angle = $\cot^{-1} \frac{(V_m)}{(V'\theta)}$
 - β^* - Metal angle: angle between tangent to mean camber line and meridional direction
 - γ - Specific Heat Ratio or Blade chord angle: angle between chord and axial direction
 - δ^0 - Deviation angle - exit air angle minus metal angle at trailing edge
 - δ - Total Pressure/Standard Day Total Pressure
 - ϵ - Angle between tangent to streamline projected on meridional plane and axial direction
 - θ - Total Temperature/Standard Day Total Temperature
 - η - Efficiency
 - σ - Solidity = $\frac{b}{s}$
 - $\bar{\omega}$ - Loss coefficient for rotor:
- $$\bar{\omega} = \frac{P_{01}' \left(\frac{T_{02}'}{T_{01}'} \right)^{\frac{\gamma}{\gamma-1}} - P_{02}'}{\frac{1}{2} \rho_1' V_1'^2}$$
- for stator:
- $$= \frac{P_{01} - P_{02}}{\frac{1}{2} \rho_1 V_1^2}$$
- ρ - Density

APPENDIX A (Cont'd.)

Subscripts

avg	- Average
ad	- Adiabatic
CORR	- Corrected to standard day
in	- Inlet
LE	- Leading edge
m	- Meridional (velocity), mean camber line (angle)
p	- Profile (loss); polytropic (efficiency)
TE	- Trailing edge
z	- Axial component
θ	- Tangential Component
0	- Total Condition
1	- Station into rotor or stator along leading edge
2	- Station out of rotor or stator along trailing edge
3	- Station out of stage

Superscripts

'	- Relative to rotor
*	- Designates blade metal angle

APPENDIX B

FLOW FIELD CALCULATION PROCEDURES

The aerodynamic flow field calculation used in this design assumes axisymmetric flow and uses solutions of continuity, energy, and radial equilibrium equations. These equations account for streamline curvature and radial gradients of enthalpy and entropy but neglect viscous terms. Calculations were performed on stations oriented at an angle γ with respect to the axial direction.

$$\frac{1}{2} \frac{\partial V_m^2}{\partial m} \cos(\lambda - \epsilon) - \frac{V_m^2}{R_c} \sin(\lambda - \epsilon) \frac{V^2}{r} + \frac{1}{\rho} \frac{\partial P}{\partial r} = 0$$

$$R_c = \frac{\partial \epsilon}{\partial m} = \text{streamline radius of curvature}$$

Enthalpy rise across a rotor for a streamline, ψ , is given by the Euler relationship:

$$H_{\text{Rotor}} = (U_2 V_{\theta 2}) - (U_1 V_{\theta 1})$$

Weight flow is calculated by the continuity equation:

$$W = 2\pi \int_{y_{\text{hub}}}^{y_{\text{tip}}} \bar{K} V_m \frac{\sin(\lambda - \epsilon)}{\sin \lambda} y dy$$

where \bar{K} is the local blockage factor and y is the length along the calculation station from the centerline to the point of interest.
